"Chemical Compounds"

This invention relates to novel intermediates in the production of vitamin D analogues and a method 5 for their production.

In the past modified vitamin D derivatives have been prepared through modification of sterol precursors which are then converted into vitamin D derivatives through a standard series of steps, 10 normally preliminary conversion of $\Delta^{5,7}$ dienes followed by irradiation of the dienes to give D vitamins. These procedures have serious flaws. First, all 15 of the available methods for the synthesis of $\Delta^{5,7}$ dienes tend to give mixtures of products or require a number of steps and proceed in relatively low yield. The second difficulty is that the only known transformation of the 5,7 dienes into the vitamins involves irradiation followed by thermal equilibration. Irradiation intrinsically gives rise to a mixture of byproducts. 20 This limits the yield of the desired vitamin and furthermore complicates its recovery in pure form.

Previous attempts to modify the 17-side chain of vitamin D compounds have been unsuccessful due to instability problems. We have now found that 25 vitamin D₂ and related compounds can be converted to a protected form capable of withstanding the reaction conditions necessary for oxidative cleavage of the 22,23-double bond to form a 22-aldehyde which can then be converted to other derivatives as described 30 hereinafter. In particular, we have found that vitamin D₂ compounds in either the cis or trans configuration can be stabilised by formation of a Diels Alder dienophile adduct which can subsequently be reconverted to the trans form of the vitamin after the side-chain modification. 35 The trans vitamin analogues can then be efficiently converted into the active cis form by known reactions.

According to one feature of the present invention we provide compounds of the general formula I,

wherein R represents a hydrogen atom or a hydroxyl protecting group, Y represents a hydrogen atom or an optionally protected hydroxyl group, X represents the residue of a dienophile and either R¹ represents a halogen atom a hydrocarbylsulphonyloxy group or a group of the formula -Z-R³ (in which Z represents -O-, -S-, -SO-, -NR⁴- or -CR⁴R⁵- and R³, R⁴ and R⁵, which may be the same or different, each represents a hydrogen atom or a straight or branched aliphatic group having 1-12 carbon atoms and which may optionally carry one or more substituents) and R² represents a hydrogen atom or R¹ and R² together represent an oxo group or an optionally substituted alkylidene group, except that R¹ and R² together with the group -CH(CH₃)CH- to which they are attached do not represent a group having the branched 17β-hydrocarbyl side chain.

The above compounds are useful intermediates in the preparation of vitamin D analogues i.e. compounds of general formulae IV and IVa

- 3 -

wherein R, Y, R¹ and R² are as hereinbefore defined.

The above compounds of general formulae IV and IVa are also novel and constitute a still further feature of this invention.

The use of the compounds of general formula I in the preparation of the novel compounds of formulae IV and IVa is illustrated in the reaction scheme of the accompanying drawings, R, Y, X, R¹ and R² being as defined above. The compounds of formula I-IV may also carry further groupings.

It should be noted that the Diels Alder adduct formed from either the 5,6-cis- or the 5,6-trans-vitamin starting material exists as a mixture of two possible isomers at the 6-position. However, since the eventual removal of the Diels Alder residue always generates a compound of the 5,6- trans configuration, there is no need to distinguish between such 6-isomers or to effect their separation.

We have found that using the above procedure a wide range of groups R¹ may be introduced into the vitamin D structure. Thus, as indicated above R¹ may be a group of the formula Z-R³, where Z is -O-, -S-, -SO-, -NR⁴ or -CR⁴R⁵- and R³, R⁴ and R⁵, which may be the same or different, are each a hydrogen atom or a straight or branched aliphatic group having

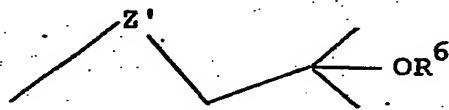

1-12 carbon atoms which may carry one or more substituents such as, for example halogen atoms (e.g. fluorine), or optionally protected hydroxyl groups.

In general it is preferred that the group R³
5 in the final products should be of the formula

(in order to provide a 17β-side chain of approximately the shape present in natural vitamin D compounds) with the possibility of substitution as described above. The heteroatoms Z, where present, do not
10 greatly change the overall shape of the side chain.

In particular, the invention enables compounds of formula IV and IVa to be prepared in which R¹ is of formula

wherein Z' represents -O-, -S-, -NH- or -SO- and
15 R⁶ represents a hydrogen atom or a hydroxyl protecting group, the 1α-position optionally carrying a hydroxyl or protected hydroxyl group, these being analogues of the active metabolite 25-hydroxy vitamin D³.

Protected hydroxyl groups may, for example,
20 be acyl groups e.g. alkanoyl groups (preferably having 1-6 carbon atoms), aralkanoyl groups (preferably having 7-15 carbon atoms), aroyl groups (preferably having 6-12 carbon atoms), cyclic ether groups or tri-hydrocarbylsilyl groups. Examples of such groups
25 include acetyl, propionyl, benzoyl and tetrahydropyranyl groups and trihydrocarbylsilyl groups having up to three C₁₋₆ alkyl, C₆₋₁₂ aryl and/or C₇₋₁₅ aralkyl groups.

The new synthetic analogues of the invention have modified vitamin D properties of interest in medicine.

The compounds of formulae IV and IVa in which

5 R¹ has the above meanings may be prepared, inter alia, by nucleophilic substitution reactions on compounds of formula IV and IVa in which R¹ represents a halogen atom, such as a chlorine, bromine or iodine atom, or a leaving group, for example a hydrocarbylsulphonyloxy

10 group O-SO₂R⁷ in which R⁷ represents, for example, an alkyl group (preferably having 1-6 carbon atoms), an aryl group (preferably having 6-12 carbon atoms) or an aralkyl group (preferably having 7-15 carbon atoms). The tosyloxy group is preferred. Alternatively,

15 the above compounds may be prepared from corresponding compounds of formula I and the dienophile group X removed subsequently. Since, however, the nucleophilic substitution reactions are mostly carried out in the presence of a base and since the protected compounds

20 of formula I are less stable to base than the parent trienes of formula IV and IVa, the latter are commonly preferred substrates.

In the formation of 22-thia compounds (in which Z is -S-), the nucleophilic reagent is conveniently

25 the thiol of formula R³XH reacted in an inert solvent such as tetrahydrofuran in the presence of a non-nucleophilic base, for example an inorganic base such as sodium hydride or an organic base such as pyridine.

30 The corresponding sulphoxides (Z= -SO-) may be prepared by oxidation of the thia-compound (Z= -S-), for example using a peracid or salt as oxidising agent, e.g. a periodate. Mixtures of the (R) and (S) sulphoxides are normally formed and the invention

35 extends to these separately and in admixture.

The 22-oxa compounds of formula IV or IVa may be prepared by reaction of an alcohol of formula I, IV or IVa in which R¹ is OH, with an alkylating agent

or alternatively by reaction of a reactive derivative thereof, with an alcoholate; these reactions are followed by deprotection when a compound of formula I is used. The reactive derivative may, for example,

5 be a halide such as an iodide, or a hydrocarbylsulphonyloxy derivative, such as a tosyloxy derivative, the alcoholate being, for example, an alkali metal or thallium alcoholate of the alcohol R^3OH . It is preferred, however, to react the compound of formula I, IV or

10 Va in which R^1 is OH with an epoxide. This generates a side chain carrying a hydroxyl group derived from the epoxide oxygen. Where it is desired to make 25-hydroxy-22-oxa vitamin D₃ derivatives, a suitable reagent is isobutylene epoxide.

15 The reaction is advantageously effected in an inert solvent, e.g. a hydrocarbon solvent such as benzene, in the presence of a non-nucleophilic base, conveniently an alkali metal t-alkoxide in the presence of a phase transfer agent such as a crown ether. Under such

20 basic conditions, we have found it especially preferred to effect the reaction on a starting compound of formula IV or IVa, since the trienes are, as indicated above, more stable to these conditions than the dienophile-protected compounds of formula I.

25 The 22-aza compounds of formula I, IV or IVa may be prepared by reaction of a reactive derivative of an alcohol of formula I, IV or IVa in which R^1 is OH, for example a halide such as an iodide, or a hydrocarbylsulphonyloxy derivative such as a tosyloxy

30 derivative, with an amine of formula R^3R^4NH . Due to the basicity of the reagent, a substrate of formula IV or IVa is preferred. Where the amine is liquid it is preferably reacted without added solvent.

The 22-aza derivatives may often conveniently

35 be isolated as N-acylates, such as N-acetates, which may be formed by reaction with an appropriate acid anhydride.

The 22-hydrocarbylsulphonyloxy derivatives of formulae I, IV and IVa used in the above reactions may be prepared by reacting the corresponding alcohol with the appropriate hydrocarbylsulphonyl halide,

5 e.g. tosyl chloride in the presence of a base such as pyridine. Best results have been obtained by effecting this reaction on a compound of formula I in which X is SO_2 , and removing the SO_2 residue by thermolysis, as described hereinafter.

10 The compounds of formula I, IV or IVa in which Z in R^1 is CR^4R^5 may be prepared by reacting compounds of formula I, IV or IVa carrying a hydrocarbylsulphonyloxy group R^1 , e.g. a tosyl group, with carbon nucleophiles. Suitable carbon nucleophiles are Grignard reagents

15 reacted in the presence of a copper catalyst, e.g. a cuprous salt. Thus, for example, 25-hydroxy vitamin D₃ and the 1 α -hydroxy derivative thereof may be prepared by reacting an appropriate hydrocarbylsulphonyloxy derivative of formula I, IV or IVa with a Grignard

20 reagent of the formula

(where R⁶ has the above meaning) in tetrahydrofuran in the presence of cuprous iodide.

For the production of an alcohol of formula 25 I in which R¹ is OH, for use in the preparation of the above novel vitamin D derivatives, the formyl group in the corresponding aldehyde of formula I (wherein R¹ and R² together represent oxo) must be reduced.

30 We have found that this can be effected readily, often in essentially quantitative yield, by reaction with a metal hydride reducing agent such as an alkali metal borohydride, e.g. sodium borohydride. It is noteworthy that this reduction retains the original 35 configuration at the 20-carbon atom. Such alcohols are also new compounds.

Compounds of formula I, IV or IVa may also be prepared in which R¹ is a divalent alkylidene group, which may carry substituents as described above for R³. Thus, for example, the aldehyde of formula I (wherein R¹ and R² together represent oxo) may be reacted with an ylide, for example a Wittig reagent which may be represented by the general formula

wherein the groups R⁸, which may be the same or different, 10 are alkyl (preferably C₁₋₆), aralkyl (preferably C₇₋₁₅) or aryl (preferably C₆₋₁₂) groups and R^{1A} is an alkylidene group (preferably having 1 to 8 carbon atoms) and may carry substituents as described for R³ above.

15 The Wittig reagent will normally be formed in situ by reaction of a quaternary salt thereof with a strong base in an inert solvent. Suitable bases include hydrocarbyl lithium compounds such as phenyl lithium and n-butyl lithium. Suitable 20 solvents include ether solvents such as tetrahydropyran and diethyl ether. The aldehyde of formula I is preferably added immediately after the Wittig reagent has been formed.

The phosphonium salt precursor of the appropriate 25 Wittig reagent for formation of the correct 17 β -side chain of 25-hydroxy vitamin D₃ may, for example be prepared by reaction of isobutylene epoxide with methylenetriphenylphosphorane; the initially formed product in which R⁵ is H may if desired be protected, 30 for example by formation of a tetrahydropyranyl or trihydrocarbylsilyl derivative. The phosphorane is preferably prepared by reaction of methyltriphenyl-phosphonium bromide in a cyclic ether solvent such as tetrahydrofuran in the presence of a strong base 35 such as phenyl or n-butyl lithium, the isobutylene epoxide then being reacted in situ with a second equivalent of base. We have found the phosphonium bromide initially produced to be difficult to isolate

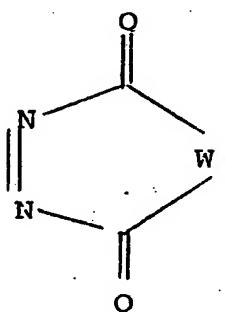

and purify but that conversion to a tetraphenylborate salt enabled a relatively pure product to be obtained.

If it is desired to form a saturated side-chain, selective reduction of the newly formed 22,23-double bond is required. This was unexpectedly found to be possible using hydrogenation over 5% palladium on charcoal. It is noteworthy that this reduction restores the desired, "natural" configuration at the 22- and 23- carbon atoms. This route thus provides a further method of preparing compounds of formula I, IV or IVa in which R¹ is - CR³R⁴R⁵, as defined above.

It will be seen that the compounds of formula I in the above reaction scheme are key intermediates in the production of the new vitamin D analogues according to the invention. By way of illustration their preparation is now described in detail starting from vitamin D₂ or its 5,6-trans isomer.

The compound of formula III may be prepared by reaction of a vitamin D₂ compound of formula IIa or IIb with a dienophile whereby the desired divalent grouping X is introduced.

The dienophile may, for example, be SO₂ or a diacylazo compound. Preferred azo dienophiles are cyclic azo compounds such as phthazine diones or triazoline diones; in general these may be represented by the formula V,

(V)

where W is a divalent aromatic carbocyclic group such as a 1,2-phenylene group or a group $\text{>} \text{N}-\text{R}^9$ where R^9 is an aryl group such as a phenyl group. The divalent aromatic group or the aryl group R^9 may 5 carry substituents, for example C_{1-6} alkyl or alkoxy groups, halogen atoms or nitro groups. Derivatives of formula III in which X is of formula V are also new compounds.

Where the dienophile is SO_2 , this may simply 10 be reacted with the vitamin D_2 compound in a suitable solvent, for example aqueous media capable of dissolving the vitamin. A well stirred mixture of water and a hydrocarbon solvent such as benzene is particularly useful. Basic conditions are preferably used, e.g. 15 using an inorganic base such as an alkali metal bicarbonate. Where the dienophile is a cyclic azo compound of formula V in which W is a group $\text{>} \text{N}-\text{R}^9$, this may be added to the starting vitamin D_2 compound in solution in a suitable solvent such as ethyl acetate. Where 20 W is a divalent-1,2-arylene grouping as in phthalazine 1,2-dione, however, this is preferably formed in situ by oxidation of the corresponding cyclic hydrazide, e.g. phthalhydrazide. Thus the vitamin D_2 compound may be reacted in solution in an inert solvent such 25 as a halogenated hydrocarbon with the cyclic hydrazide in the presence of an oxidising agent such as lead tetraacetate/acetic acid.

After formation of the adduct of formula III, the 22,23-double bond may be cleaved to form the 30 22-formyl derivative of formula I by known oxidative techniques such as permanganate/periodate, osmate/periodate or, most preferably ozonolysis. We have found that this reaction proceeds selectively in high yield with little cleavage of the 7,8-double bond and, 35 in particular, with no disturbance of the stereochemistry at the 20-position.

Ozonolysis may be effected by passing ozone, preferably diluted with a further gas such as oxygen,

through a solution of the compound of formula III in a solvent therefor to form an ozonide which is then reductively cleaved by a suitable reducing agent.

A suitable solvent is, for example, a halogenated

- 5 hydrocarbon such as dichloromethane, a ketone, e.g. methyl ethyl ketone or acetone or an alcohol such as methanol or ethanol. A mixture of dichloromethane and methanol gave especially good yields. The reducing agent may be present during the reaction or added
- 10 after ozonide formation is completed. Thus, for example tetracyanoethylene may be present in solution in acetone during ozonolysis. While reducing agents such as dimethyl sulphide may be used to reduce the ozonide after its formation, preferred reagents are
- 15 trivalent phosphorus compounds such as triphenylphosphine.

Where an alcohol solvent is used, the aldehyde product of formula I may form an acetal derivative with the alcohol. This may, however, readily be cleaved hydrolytically, for example using an aqueous base e.g. sodium bicarbonate. The reaction is preferably carried out at low temperatures, for example -78°C.

- After modification of the 17-side chain, the dienophile residue X may be removed to yield, as indicated above, a 5,6-trans vitamin of general formula IV. The removal of the residue X will be effected in different ways, depending on its nature.

- Where X is SO_2 , it is conveniently removed by thermolysis under basic conditions, e.g. in the presence of a hydroxylic solvent such as an alcohol, e.g. ethanol, containing a base such as an alkali metal carbonate, e.g. sodium carbonate.

- Where X is a group of formula V, removal can readily be effected by removal of the $-\text{CO}-\text{W}-\text{CO}-$ moiety, for example by basic hydrolysis or treatment with hydrazine, followed by mild oxidation of the unsubstituted vitamin hydrazide so formed to the corresponding azo-compound which spontaneously decomposes to yield the required 5,6,-trans vitamin. Basic hydrolysis

can be effected using strong alkali such as sodium or potassium hydroxide, for example in solution in an alcohol such as methanol, or by treatment with an amine such as triethylamine. The preferred method, 5 however, is treatment with hydrazine which produces the desired hydrazide in high yield; this reaction has not previously been described for decomposition of such Diels-Alder adducts. Oxidation may be effected using reagents capable of oxidising hydrazo compounds 10 to azo compounds, for example ceric, cupric, ferric, ferricyanic or periodate salts or air. A preferred mild reagent, however, is a diaryl telluroxide such as dianisyl telluroxide, preferably used with a re-oxidant such as 1,2-dibromotetrachloroethane and 15 a base such as K_2CO_3 as described in our British Patent Specification No, 2058758A.

Where a $\Delta\alpha$ -hydroxy vitamin D compound is required, the modified 5,6-trans-vitamin compound of formula IV, which carries the desired 17-side chain, optionally 20 protected, may be subjected to $\Delta\alpha$ -hydroxylation, using the procedure of our South African patent No. 79/5958. Thus, the 5,6-trans vitamin compound may be reacted with a selenite ester, preferably formed in situ by reaction of selenium dioxide and an alcohol 25 such as methanol. The quantity of selenium compound may be reduced if a re-oxidant is employed, for example a periodate salt or N-methyl morpholine 1-oxide.

Alternatively, a reactive derivative of a 22-hydroxy derivative of formula I or IV above may be 30 $\Delta\alpha$ -hydroxylated by the above procedure and the desired side-chain built up subsequently.

The 5,6-trans vitamin D compound of formula IV, after modifications such as those described above, may readily be isomerised in high yield to a required 35 active cis-vitamin compound by known techniques, for example by irradiation in the presence of iodine or diphenyl selenide or, preferably, a triplet photo-sensitizer having a triplet energy of the order of 45+

5 Kcal per mole, such as anthracene, acridine or phenazine. To avoid isomerisation to undesired tachysterol derivatives, acid conditions should be avoided and the photoisomerisation is preferably effected

5 in the presence of a base such as triethylamine.

Where protected hydroxyl groups are present in the vitamin product, these may be removed by conventional methods. In general, the vitamin structure is somewhat sensitive to acids, but is resistant

10 to basic conditions and the latter are advantageously used. Acyloxy groups can thus be removed using alkali metal hydroxide in an alcohol solvent such as methanol. Silyl groups may be removed by treatment with quaternary ammonium fluorides such as tetra-n-butylammonium

15 fluoride. Since most of the reactions described above can be applied to compounds having unprotected hydroxyl groups, protecting groups may be removed, if desired, at various stages. Although the vitamins are resistant to bases (and sensitive to acids), the dienophile

20 adducts tend to be sensitive to bases and relatively resistant to acids. Consequently, acid conditions may be used to deprotect hydroxyl groups at stages where the dienophile residue X is present.

In general, most of the stages described above

25 proceed in excellent yield. When conditions are optimised, yields of the order of 80% or more at each stage have been achieved. This renders the overall yield of modified vitamin, starting from vitamin D₂, markedly better than those achieved using

30 many previously suggested routes.

The following Examples are given by way of illustration only:-

Microanalyses and mass spectra were obtained by the staff at the Institut de Chemie des Substances Naturelles du CNRS, Gif-sur-Yvette, France. Melting points were determined using either a Kofler block, Mel-Temp or Fisher-Johns apparatus and are uncorrected. Optical rotations were measured at room temperature using a Rudolph Photoelectric Polarimeter, Model 70, and are reported for chloroform solutions unless otherwise stated. UV spectra were recorded using a Carey 11 spectrophotometer and are reported for ethanol solutions. The molar extinction coefficient (ϵ) for these absorbances are given in parenthesis. IR spectra were recorded using a Perkin-Elmer 137 "Infracord" spectrophotometer and are reported for KBr discs unless otherwise stated. Absorbance characteristics are denoted by s = strong, m = medium, w = weak, sh = shoulder, br = broad. $^1\text{Hnmr}$ spectra were determined at 60MHz on a Varian T-60 spectrometer. NMR characteristics are denoted as s = singlet, d = doublet, tr = triplet, q = quartet, m = multiplet, W = peak width at half height and are reported for CDCl_3 solutions, unless otherwise indicated, with tetramethylsilane as internal standard, as values of δ (ppm downfield of TMS).

Thin layer chromatography (tlc) was carried out on 250μ silica gel GHLF "Uniplates" (Analtech, USA); and preparative layer chromatography (plc) on 1mm silica gel GF-254 "Uniplates" (Analtech, USA). "Chromatography" refers to medium pressure liquid chromatography carried out using E. Merck silica gel 60H. High performance liquid chromatography (HPLC) was carried out using Waters Associates silica gel "Porasil A" packed in two 2 ft x 3/8 inch stainless steel columns,

and a Waters Associates chromatograph, equipped with a 6000 psi pump and a differential refractometer detector. Ozone was generated from a Towers Ozone Apparatus GE-150. Selective ozonolysis requires vigorous mixing of the dissolved substrate and the oxygen-ozone gaseous mixture. A "Vibromixer" (Chemapag, Switzerland) equipped with a stainless steel gas inlet/stirrer was particularly useful for this purpose. This equipment was also used for the formation of the phthalazine-1,4-dione Diels-Alder adducts of vitamin D.

A 200W Hanovia medium pressure mercury vapour lamp (654A36) was used as irradiation source for 5,6-double bond photoisomerisation reactions.

Reactions on calciferol substrates were routinely performed under an inert, argon atmosphere. Calciferols were stored at -20°C, under argon, in the dark, as either crystalline solids or (where possible) ether solutions. Solvents used were reagent grade unless otherwise stated.

Aqueous work-up refers to partition between an organic solvent and water, followed by sequential washing with a 5% aqueous sodium bicarbonate solution and a saturated aqueous sodium chloride solution. The organic solution was dried using either anhydrous $MgSO_4$ or anhydrous Na_2SO_4 , and the solvent removed on a rotary evaporator. Acid work-up refers to partition between an organic solvent and water, followed by sequential washing with a 4% aqueous HCl solution; 5% aqueous sodium bicarbonate solution, etc. as for aqueous work-up.

10 (a) Preparation of isobutylene epoxide

To methylallyl chloride (200 ml), 186g) cooled in an ice bath was added 80% H₂SO₄ (H₂SO₄, 95%, 109 ml; H₂O, 40 ml, 1 eq) over a 30 min period. The temperature of the mixture was maintained between 5-10°C. After a further 3 hr the mixture was added to ice and diluted to a total 15 volume of approx. 100 ml. The layers were separated and the organic residue distilled to remove the by-product β,β-dimethylvinyl chloride and unreacted starting material. These materials are removed below 80°C. The darkly coloured distillation residue is 1-chloro-2-methyl-propan-2-ol (128a) δ 3.47 (s, 2H), 2.97 (s, 1H, exchanges with D₂O), 1.32 20 (s, 6H). This material was used without further purification.

To a 500 ml round bottom flask containing KOH (200g) in water (125 ml) at 80°C and fitted with a mechanical stirrer and condenser, was added dropwise the crude chlorohydrin. The crude epoxide distilled directly from the reaction mixture. Redistillation gave isobutylene 25 epoxide (48g, 35%) b.p. 51°C (lit.^{128c} 52°C); ¹Hnmr δ 2.6 (s, 2H), 1.33 (s, 6H).
